Notch receptors signaling is required for optimal T-cell activation and function. T-cell receptor (TCR) engagement can activate Notch receptors in T-cells in a ligand-independent fashion. In this study, we examined the role of adenosine A2A receptor (A2AR) signaling pathway in regulating the activity of Notch1 induced by TCR stimulation in CD8+T-cells. A selective A2AR agonist decreased Notch1 protein expression and Notch1 cleavage, and reduced transcripts of Notch1-target genes *Hes1* and *Myc* in activated CD8+T-cells. Inhibition of TCR-induced Notch1 expression by an A2AR agonist was accompanied by increased cAMP concentration and mimicked by forskolin. This effect was associated with reduced IFN- γ and granzyme B production. The effect of an A2AR agonist was abrogated by a selective A2AR antagonist and absent in CD8+T-cells harvested from A2AR $-/-$ mice. Stimulation of A2AR reduced Notch1 receptor levels by inhibiting upstream TCR signals, including ZAP70 phosphorylation, in turn impairing the generation of the active Notch1 intracellular domain (N1ICD). Direct activation of PKC with PMA and ionomycin bypassed A2AR-induced Notch1 inhibition. Overexpression of N1ICD in CD8+T-cells prevented the suppressive effects of an A2AR agonist on proliferation and cytokine release during activation. Our results identify the A2AR signaling pathway as an important regulator of TCR-induced Notch1 receptor activation in CD8+T-cells, and Notch as an important target of the immune suppressive effects of A2AR. We propose a mechanism whereby A2AR impairs CD8 T-cells function through inhibition of Notch1 receptor activation.

INTRODUCTION

Notch signaling plays a pivotal role in the differentiation and function of several T-cell subsets [reviewed in (1–4)]. Notch proteins (Notch 1–4) are heterodimeric transmembrane receptors that are activated by engagement of transmembrane ligands (Delta-like 1, 3, 4, and Jagged 1, 2, although Delta-like 3 is likely an inhibitory ligand) (5). The interaction of Notch receptors with their ligands leads to subunit separation, followed by a trans-endocytosis of the Notch extracellular domain. This facilitates the cleavage of the Notch transmembrane subunit by metalloproteases of

the ADAM family, which is followed by a second cleavage within the transmembrane domain by the γ -secretase complex. This generates the active intracellular domain of Notch (NICD) (1, 2, 6). NICD translocates into the nucleus where it associates with the transcriptional repressor CSL (CBF1-Suppressor of Hairless-LAG1), recruiting a co-activator complex, to modulate the transcription of several genes (7). In T-cells, ligand-independent activation of Notch1 receptor can be triggered through T-cell receptor (TCR) signals (8–11), through mechanisms that require receptor endocytosis. Notch1 can upregulate its own expression in T-cells (12). TCR-induced up-regulation of Notch1 expression in peripheral T-cells is associated with increased proliferation and cytokine production, including IFN- γ (8), or the expression of the transcriptional regulator comesodermin (EOMES), which in turn regulates the expression of CD8 effectors perforin and granzyme B (10). Transgenic expression of Notch1 renders CD8 T-cells resistant to tumor-induced immune suppression (13). Pharmacological inhibitors of γ -secretase, which prevent the generation of NICD (14, 15), reduce proliferation and cytokine release from TCR-activated T-cells in a concentration-dependent manner (8, 10). Notch2 also contributes to the activity of cytotoxic T-cells, controlling directly the transcription of granzyme B, independently of EOMES (16). The expression of Notch2 can be also up-regulated during T-cell activation and can, redundantly with Notch1, modulate proliferation and IFN- γ production in CD8+T-cells (13).

Adenosine is an ATP metabolite that increases in the extracellular space in response to hypoxia and tissue injury, acting as an anti-inflammatory mediator that limits inflammation-induced damage (17). Adenosine can exert profound immunosuppression by acting on both lymphoid (18) and myeloid cells (19). The A2A receptor (A2AR) belongs to the family of adenosine receptors and is the predominant adenosine receptor type expressed in T-cells (20, 21). This is a high-affinity, Gs-coupled receptor that upon activation increases cyclic AMP (cAMP), which in turn activates protein kinase A (PKA). Stimulation of A2AR suppresses TCR signaling in a cAMP-dependent manner (22–26). Inhibition of TCR signaling by A2AR agonists is associated with reduced cytokine production, including interleukin-2 (IL-2) and interferon- γ (IFN- γ), and decreased cytotoxicity and proliferation (22–27). Selective A2AR agonists may be used for the treatment of inflammatory diseases (28). Conversely, because A2AR in tumors contributes to induce profound immunosuppression, A2AR antagonists are considered potential novel cancer immunotherapeutics (29).

Given the crucial role of A2AR signaling in limiting CD8+ T-cell responses, we evaluated its effects on Notch1 expression and signaling. We demonstrate that A2AR stimulation inhibits TCR-induced Notch1 expression and cleavage in activated CD8+T-cells, describing a novel mechanism through which adenosinergic molecules can suppress CD8+T-cells functions via A2AR.

MATERIALS AND METHODS

CD8+ Cells Isolation and Activation

Splenocytes were collected aseptically from the spleens of naïve C57BL/6 mice (6–10 weeks old) (Charles River, Lecco, Italy)

or from A2AR gene-deficient (*A2AR*^{−/−}) C57BL/6-background mice (6–10 weeks old), kindly provided by M. Sitkovsky (Northeastern University). CD8+ T-cells were enriched with a negative selection kit (StemCell Technologies), according to manufacturer's instructions. Experiments were also performed in CD8+T-cells conditionally expressing transgenic Notch1 intracellular domain (N1IC CD8+T-cells) or floxed control cells (N1IC^{f/f} CD8+T-cells) isolated, respectively, from previously described N1IC mice and N1IC^{f/f} mice (13). Isolated cells, cultured in RPMI 1640 medium supplemented with 10% FBS, 4 mM L-Glutamine, 50 U/ml penicillin, 50 μ g/ml streptomycin and 50 μ M 2-mercaptoethanol, were activated in plates coated with anti-mouse CD3 ε (1 μ g/ml; clone 145-2C11) and anti-mouse CD28 (0.5 μ g/ml; clone 37.51) antibodies up to 72 h or left unstimulated (NS). In specific sets of experiments, CD8+ T-cells were activated with 50 ng/ml phorbol 12-myristate 13-acetate (PMA) and 200 ng/ml ionomycin (both from Sigma-Aldrich) or left unstimulated (NS).

Cell Treatments

Cells were incubated with 1 μ M A2AR agonist CGS-21680 (Tocris), 1 μ M A2AR antagonist ZM-241385 (Tocris), 1 μ M γ -secretase inhibitor PF-3084014 (SelleckChem) or with 10 μ M adenylate cyclase stimulator Forskolin (Sigma-Aldrich), alone or in combination, 15 min before activation with anti-CD3 ε /CD28 antibodies or PMA and ionomycin. PF-3084014 was dissolved in DMSO, whilst the other agents were solubilized in PBS (vehicle). Control cells (Ctr) received vehicle before activation as described above. In specific experiments, cells were incubated with the above agents 24 h after CD3 ε /CD28-stimulation.

Proliferation Assays

To measure proliferation, 5×10^5 isolated CD8+ T-cells were labeled with 1 μ M carboxyfluorescein diacetate succinimidyl ester (CFDA-SE, Life Technologies) for 10 min at 37°C. Cells were then washed to remove excess CFSE and then treated with 1 μ M CGS-21680, 1 μ M PF-3084014, or 10 μ M Forskolin before adding anti-CD3 ε and anti-CD28 antibodies for 72 h. Proliferation was assessed by measuring CFSE fluorescence by flow cytometric analysis on a FACSCalibur cytometer (BD Biosciences). Data were analyzed using CellQuest software.

ELISA Assays

Granzyme B and IFN- γ concentrations were measured in CD8+ T-cells supernatants after 72-h treatments as described above, by using specific ELISA kits (Thermo Fisher Scientific) according to the manufacturer's instructions.

Western Blot Analysis

1×10^6 cells treated as described above were collected, washed in ice-cold PBS and lysed in RIPA buffer to which were freshly added 1 mM Protease Inhibitor Cocktail (Thermo Scientific), 1 mM NaF and 1 mM sodium orthovanadate (all the reagents used for the lysis buffer were EDTA-free). Equal amounts of proteins were electrophoretically separated in SDS-PAGE gels and then transferred to PVDF membranes (Immobilion-FL Transfer Membrane). Bovine serum albumin (5% BSA,

Sigma) was used to block non-specific binding sites. The following primary antibodies were used: anti-Notch1 (which specifically detects the Notch1 intracellular domain N1ICD, Val1744; D3B8), anti-Notch1TM, (to detect the transmembrane Notch1 domain, D1E11) (both from Cell Signaling), anti-pZAP70 (pY319.17A) or anti-GAPDH, anti-β-tubulin or anti-actin as controls (Santa Cruz Biotechnology). After incubation with appropriate secondary antibodies, immune-reactive protein bands were detected by enhanced chemiluminescence reagents (Amersham Pharmacia Biotech, UK) and analyzed by Las4000 (GE Healthcare Life Sciences). The optical density of protein bands detected by Western blotting was calculated with ImageQuantTL (GE Healthcare).

Quantitative Real-Time RT-PCR

Total RNA was isolated from treated cells using an RNeasy Mini kit (Qiagen) following the manufacturer's instructions. Reverse transcription was performed using the First strand cDNA synthesis Kit (Fermentase Life Science Co.). cDNAs were amplified by real-time PCR using iTaqTM SYBR Green Supermix with ROX (Bio-Rad). Primer sequences were:

Notch1(Forward): AGCGGGGTATGCAAGGAGTC,
(Reverse): CTCGCAGGTTTGACCTTGC;
Hes1(Forward): CTGGTGCTGATAACAGCGGAATC,
(Reverse): AGTGATCGGTAGCACTATTCCAGG;
Myc(Forward): GCAGATCAGCAACAACCGCA, (Reverse): CCAAGACGTTGTGTGCCG;
IFN γ (Forward): TGCATCTGGCTTGCAGCTC, (Reverse): GGCTTCAATGAGTGTGCCGT.
Rpl3a(Forward): GGAGGGCAGGTTCTGGTAT, (Reverse): TTCACACGCGTACGACCACCA.

Samples were run in triplicate in a 96 well Optical Reaction plate (Applied BioSystems). The PCR reaction conditions were: 50°C for 2 min, 95°C for 5 min, 35 cycles of 95°C for 30 s, 59°C for 1 min, 72°C for 1 min, followed by dissociation step. Granzyme B RT-PCR analysis was performed by using Taqman primers Mm00442837_m1 and GAPDH: Mm99999915_g1 as housekeeping gene (Applied Biosystems). Results were analyzed using the 7,300 system Software (Applied BioSystems).

cAMP Assays

cAMP levels were measured with the cAMP assay kit (Abcam), according to the manufacturer's instructions. cAMP levels were determined in 1×10^6 CD3ε/CD28-stimulated CD8+ T-cells pre-incubated with 1 μM CGS-21680 or 10 μM Forskolin. 10 min later, cells were incubated with 0.1 M HCl at room temperature for 20 min. After gentle pipetting, samples were centrifuged for 10 min and supernatants collected. Samples were then assayed for cAMP levels.

Statistical Analysis

Unless otherwise stated, results are expressed as means ± SD. Data were analyzed with GraphPad Prism 6 (GraphPad Software). Two-tailed Student's *t*-test (2-group comparisons) or ANOVA (>2-group comparisons) were performed as appropriated, with Bonferroni correction for multiple

comparisons when needed. *P* values < 0.05 were considered significant.

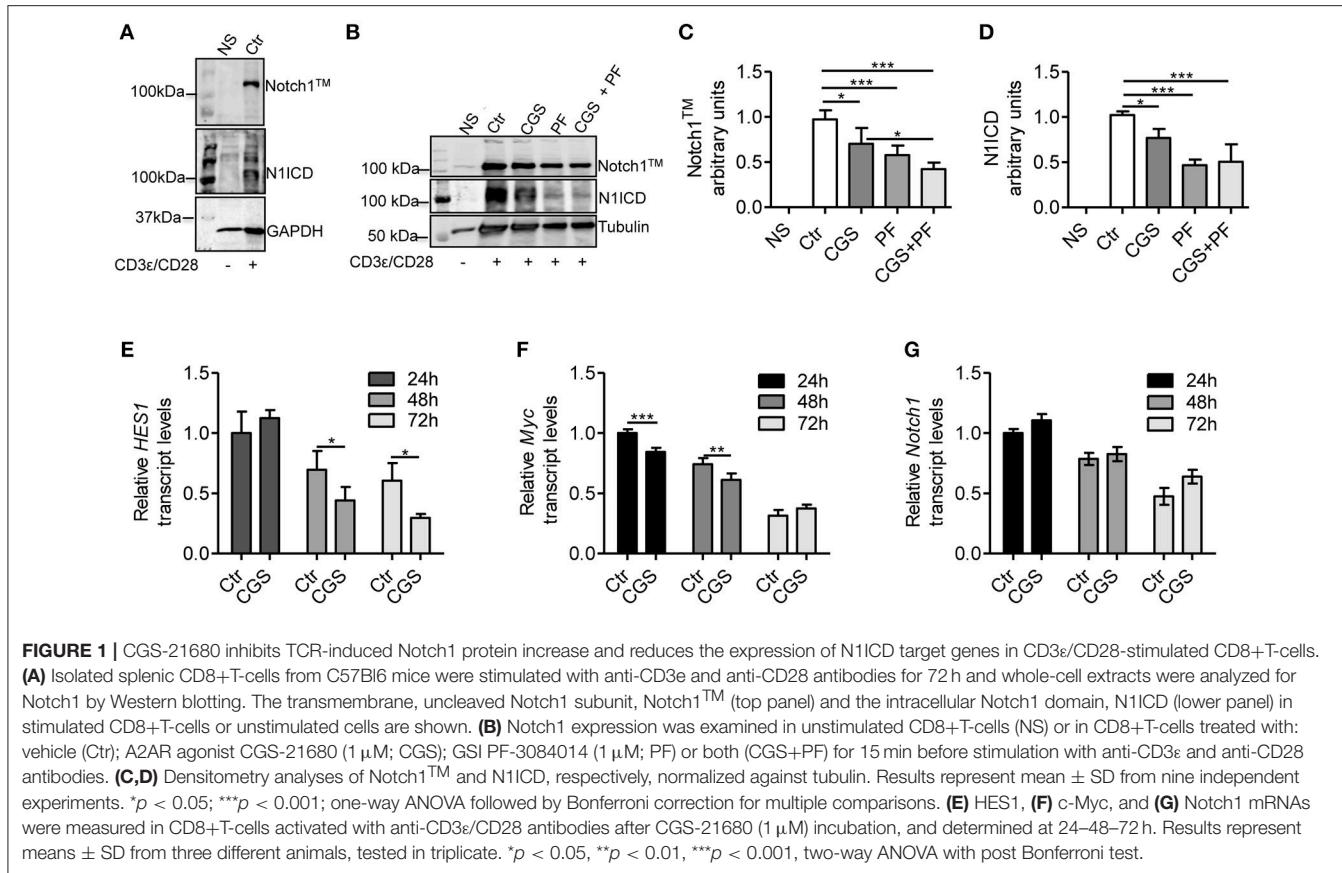

RESULTS

A2AR Stimulation Leads to Reduced Expression and Activity of Notch1 in CD3ε/CD28-Activated CD8+T-Cells

To evaluate the mechanistic interaction between A2AR and Notch signaling, we pre-incubated for 15 min mouse CD8+ T-cells with the selective A2AR agonist CGS-21680 prior to adding anti-CD3ε/CD28 specific antibodies. As Notch1 receptor proteolytic cleavage/activation is induced by TCR stimulation (8, 10, 11, 30), we evaluated the levels of Notch1 receptor proteins (the transmembrane Notch1 subunit, Notch1TM and the intracellular Notch1 domain, N1ICD) in activated CD8+ T-cells compared to unstimulated cells. Activated CD8+T-cells strongly expressed Notch1TM and N1ICD proteins, compared to non-stimulated (NS) counterparts (Figure 1A). Notably, incubation of CD8+T cells with CGS-21680 significantly reduced the expression of both Notch1TM and N1ICD (Figures 1B–D), suggesting that A2AR activation interferes with TCR signaling. As a control, we treated cells with the γ-secretase inhibitor (GSI) PF-3084014, which potently inhibits Notch1 cleavage (31). Incubation of cells with PF-3084014 (1 μM) prevented the generation of N1ICD following anti-CD3ε/CD28 stimulation (Figures 1B–D). Cells treated with PF-3084014 alone or together with CGS-21680 showed the highest Notch 1 down-regulation (Figures 1B–D).

To further investigate the effect of the A2AR agonist on TCR-induced Notch1 signaling pathway, we determined the expression of N1ICD-target genes *Hes1* (32) and *cMyc* (33). *Hes1* and *cMyc* mRNA levels were reduced in CD8+T-cells treated with CGS-21680 (1 μM) and stimulated with anti-CD3ε/CD28 (Figures 1E,F, respectively). In particular, *Hes1* mRNA levels upon TCR stimulation were significantly reduced 48 and 72 h after CGS-21680 treatment (Figure 1E). *cMyc* mRNA levels were significantly decreased at 24 and 48 h of treatment (Figure 1F). These results suggest that stimulation of A2AR decreases the expression and activation of Notch1 and N1ICD-mediated transcriptional activity in CD3ε/CD28-stimulated CD8+T-cells. The different time courses of the two transcripts may be related to different half-lives of these two transcripts or to the different mechanisms whereby N1ICD regulates the expression of *Hes1* and *cMyc* in T-cells. *Hes1* is regulated largely through a Sequence-Paired Site (SPS) closely associated with the *Hes1* transcriptional start site (34), whereas *cMyc* is regulated primarily through a distal super-enhancer whose acetylation status is highly sensitive to depletion of N1ICD (35).

To determine whether the lower levels of Notch1 protein were due to reduced mRNA synthesis, we analyzed *Notch1* transcript levels in CD8+T-cells treated with CGS21680 (1 μM) and anti-CD3ε/CD28. *Notch1* mRNA levels were unchanged in CD8+T-cells incubated with CGS-21680 compared to control cells (Figure 1G), indicating that A2AR stimulation decreases the levels of Notch1 protein without affecting *Notch1* transcription.

The Inhibitory Effect of CGS-21680 on TCR-Induced Notch1 Expression Depends on A2AR Stimulation

To confirm that the effect of CGS-21680 on Notch1 expression was dependent on A2AR stimulation, we performed experiments in presence of the A2AR antagonist ZM-241385 (1 μM), administered in combination with CGS-21680 (1 μM). Treatment with ZM-241385 (1 μM) reversed the inhibitory effect of CGS-21680 on Notch1 expression in CD3ε/CD28-stimulated CD8+T-cells (Figure 2A). To rule out off-target effects induced by the CGS-21680, we treated T cells lacking A2AR. In A2AR^{-/-} CD8+T-cells, CGS-21680 treatment did not affect TCR-induced Notch1 levels or N1ICD levels (Figure 2B), indicating that the observed CGS-21680 effects were triggered through stimulation of A2AR. No differences in the levels of Notch2, 3, or 4 were observed in A2AR^{-/-} CD8+T-cells (Supplemental Figure 1).

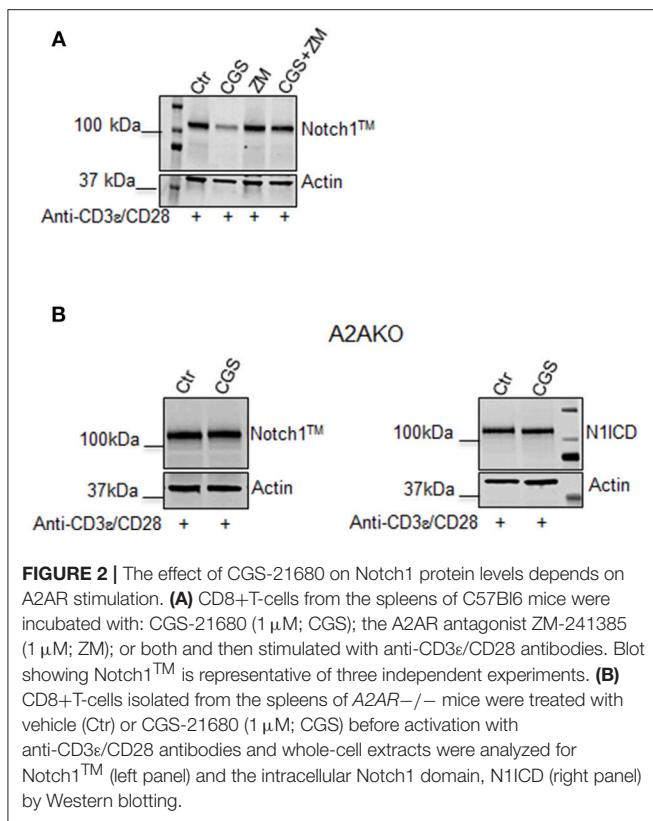

A2AR Stimulation and Notch1 Inhibition Strongly Reduce Proliferation and Cytokine Production in Activated CD8+ T-Cells

Stimulation of A2AR strongly inhibits the proliferation (22) and the effector functions of activated T-cells, including cytokine production (23–27). On the other hand, Notch1 activation promotes proliferation (8) and cytokine release (8, 10, 36) in

CD8+T-cells. We therefore investigated the cross-talk between these signaling pathways in regulating the functional properties of CD8+T-cells, by measuring proliferation and cytokine levels in cells treated with CGS-21680 alone or in combination with GSI PF-3084014 before TCR-activation. Proliferation was assessed by flow cytometry analysis after CFSE staining. The increased CD8+ T-cell proliferation induced upon stimulation with anti-CD3ε/CD28 was slightly reduced after pre-incubation with CGS-21680 or PF-3084014 (Figure 3A). Moreover, an additive anti-proliferative effect was observed after the combination of CGS-21680 plus GSI PF-3084014 (Figure 3A).

Experiments were also performed in cells treated with the A2AR antagonist ZM-241385 (1 μM). Further inhibition of A2AR signaling through ZM-241385 did not affect proliferation in anti-CD3ε/CD28-activated T cells (Figure 3A).

Transcript levels of granzyme B and IFN-γ were significantly reduced in cells treated with 1 μM CGS-21680 or 1 μM PF-3084014 and even more so after combination treatment with CGS-21680 + GSI before stimulation with anti-CD3ε/CD28 antibodies for 24 h (Figures 3B,D, respectively). Consistent with mRNA levels, the amounts of granzyme B and IFN-γ released from activated CD8+T-cells treated with CGS-21680 (1 μM) and/or PF-3084014 (1 μM) for 72 h were significantly reduced compared to control cells (Figures 3C,E, respectively). These data indicate that A2AR stimulation and γ-secretase inhibition strongly impair the functions of activated CD8+T-cells. The

effects of GCS-21680 on both granzyme B and IFN-γ were completely reversed by the A2AR antagonist ZM-241385 (1 μM) (**Figures 3C,E**, respectively).

Treatment of A2AR^{-/-} CD8+T-cells with CGS-21680 (1 μM) failed to reduce the release of either granzyme B (**Figure 3F**) or IFN-γ (**Figure 3G**), confirming that the suppressive effect of CGS-21680 on the release of these factors was completely dependent upon the presence of A2AR. Conversely, inhibition of γ-secretase with PF-3084014 led to a significant reduction of both granzyme B and IFN-γ release from activated CD8+T-cells from A2AR^{-/-} mice (**Figures 3F,G**, respectively). These data indicate that Notch effects on granzyme B and IFN-γ release are independent of A2AR.

Adenylate Cyclase Stimulation Mimics the Effects of CGS-21680 on Notch1 in Activated CD8+ T-Cells

Stimulation of A2AR increases intracellular levels of cAMP in activated T-cells (22, 26). Consistent with these reports, we observed that CGS-21680 treatment (1 μM) of CD3ε/CD28-stimulated CD8+ T-cells increased cAMP levels within 10 min (**Figure 4A**). To evaluate whether increased levels of cAMP affected TCR-induced Notch1 signaling, we used the adenylate cyclase activator Forskolin (10 μM), which significantly increased cAMP levels in activated T-cells (**Figure 4B**). Forskolin significantly decreased the expression of Notch1 proteins induced by TCR engagement in CD8+T-cells, proliferation, production of IFN-γ and granzyme B (**Figures 4C–G**). When

we combined Forskolin and GSI PF-3084014 (**Figures 4C,D**), the effect on Notch1 proteins was marked. These results suggest that cAMP-elevating agents can markedly decrease the amount of Notch1 in activated CD8+ T-cells and significantly impair Notch-dependent functions of TCR-stimulated CD8+T-cells.

Ectopic Expression of N1IC Rescues CD8+ T-Cells From the Suppressive Effects of CGS-21680

To determine the functional role of the inhibition of Notch1 signaling in the suppressive effects induced by A2AR activation, we studied CD8+T-cells from activated-CD8+T cell conditional N1IC mice (13), which over-express Notch1IC upon activation. N1IC mice were created after crossing N1IC^{f/f} mice with those expressing Cre Recombinase driven by Granzyme B promoter. Activated N1IC CD8+ T-cells or floxed controls (N1IC^{f/f}) were treated with CGS-21680 and/or GSI PF-3084014 and evaluated for proliferation or IFN-γ and granzyme B expression. Similar to the results observed in wild-type T cells, treatment of N1IC^{f/f} cells with CGS-21680 and/or PF-3084014 slightly reduced the proliferation (**Figure 5A**). Conversely, activated N1IC CD8+ T-cells showed no restriction in their proliferation after treatment with CGS-21680 or PF-3084014 or a combination of both (**Figure 5A**), suggesting that restoring Notch1 signaling in CD8+T-cells prevents the suppressive effects induced by A2AR activation.

Next, we compared the expression of IFN-γ and granzyme B in N1IC vs. N1IC^{f/f} CD8+ T-cells treated with CGS-21680, GSI PF-3084014 or both. In agreement with the key role of Notch in the effects induced by A2AR, we found that while CGS-21680 and/or PF-3084014 reduced the frequency of IFN-γ-expressing cells and the expression of granzyme B in control N1IC^{f/f} CD8+ T-cells, they had no significant effect in N1IC CD8+ T-cells (**Figures 5B,C**). Overall, these results indicate that inducible expression of Notch1 intracellular domain is sufficient to overcome the suppressive effects of A2AR agonists in activated CD8+T-cells, and support the hypothesis that Notch1 is a functionally important target of A2AR-mediated suppressive effects in these cells.

A2AR Stimulation Inhibits TCR-Induced Notch1 Activation/Expression by Blocking Proximal TCR Events

In CD4+ T-cells, TCR stimulation triggers Notch1 activation within 2 h with a peak at 6 h (11). This activation is mediated by a unique, Notch ligand-independent process that requires Notch endocytosis and signals from the TCR through Lck, ZAP70, phospholipase C gamma (PLC γ), a diacylglycerol-activated protein kinase C (presumably PKC θ), Ca $^{++}$ influx as well as ADAM10 or 17 and γ-secretase. PKC is activated by PDK1, in response to a PI3K co-activating signal from CD28 (37). We reasoned that if Notch1 activation in CD8+ T-cells is mediated by a similar mechanism, A2AR activation would suppress ZAP70 phosphorylation, while activation of PKC and Ca $^{++}$ influx downstream of ZAP70 would bypass A2AR-mediated Notch inhibition. Additionally, we hypothesized

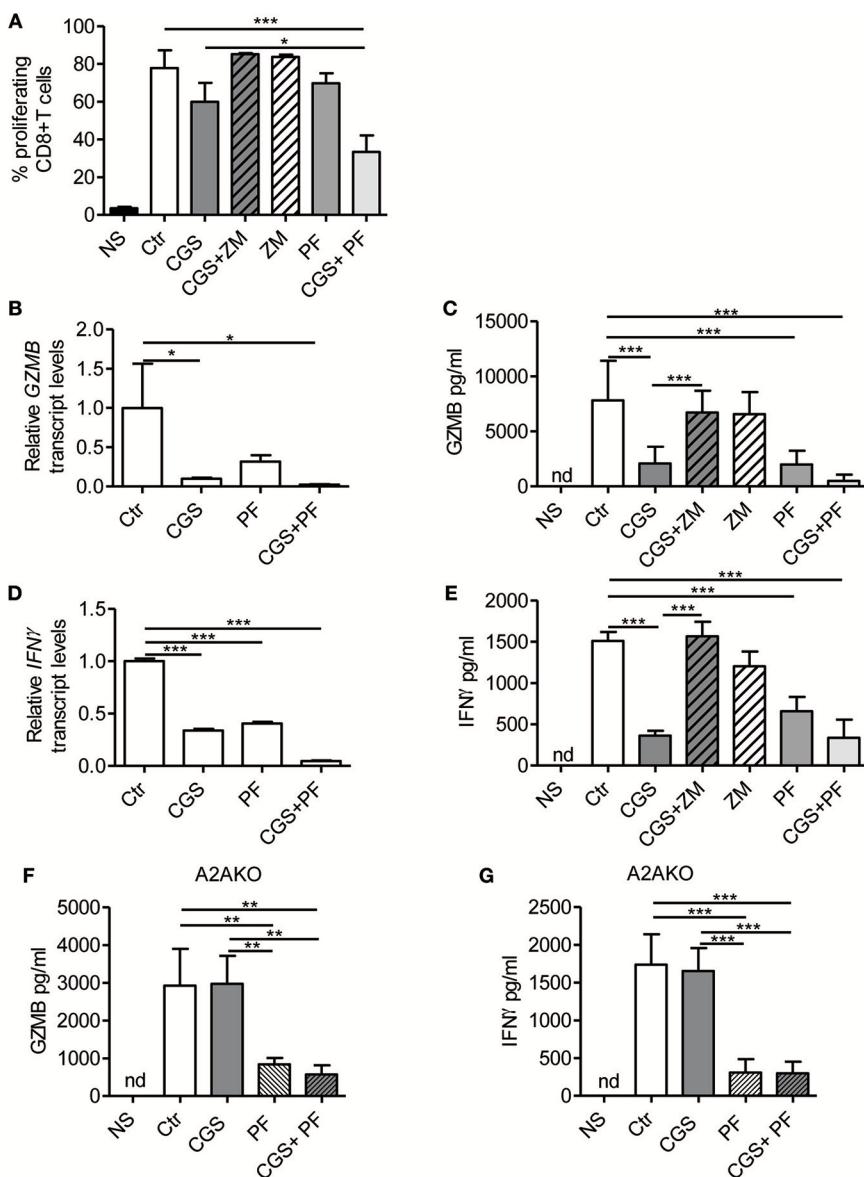

FIGURE 3 | A2AR stimulation and γ -secretase inhibition decrease CD8+T-cell effector functions. **(A)** CD8+T-cells were labeled with CFSE and then incubated with CGS-21680 (1 μ M; CGS), PF-3084014 (1 μ M; PF) or both (CGS+PF) for 15 min before stimulation with anti-CD3 ϵ /CD28 antibodies for 72 h. Proliferation was also assessed in cells incubated with the A2AR antagonist ZM-241385 (1 μ M; ZM) alone or in combination with CGS-21680 (CGS+ZM). CFSE-labeled cells were counted by flow cytometry. that A2AR agonists would be unable to block Notch1 if given after early events in TCR activation have occurred. A2AR stimulation inhibits early TCR signaling by increasing the

levels of cAMP during T-cell activation. This effect is mediated by reduced ZAP70 phosphorylation (26, 38). Consistent with these observations, we found that incubation of cells with

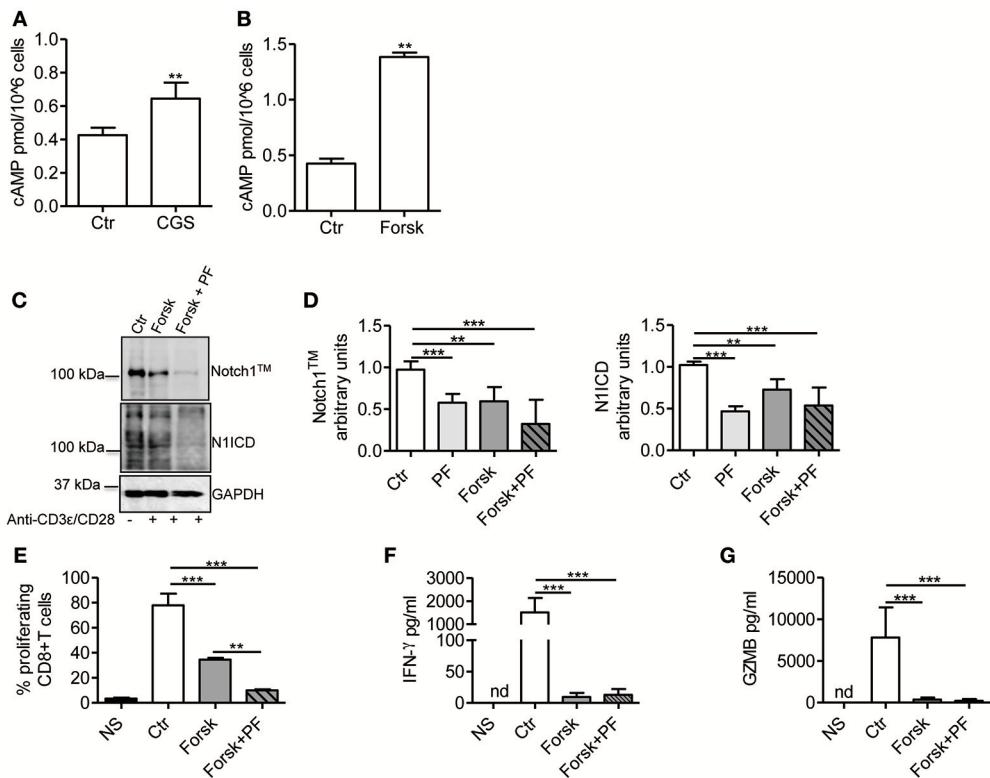

FIGURE 4 | cAMP inhibits TCR-induced Notch1 activation in CD8+T-cells. Levels of cAMP were measured in cells incubated with CGS-21680 (1 μ M; CGS) (A) or Forskolin (10 μ M; Forsk) (B) before stimulation with anti-CD3 ϵ /CD28 antibodies for 10 min. Activated CD8+T-cells (Ctr) were used as controls. Results represent means \pm SD from four different animals, tested in duplicates. ** p < 0.01; Mann-Whitney test. CGS-21680 (1 μ M) reduced Tyr319 ZAP70 phosphorylation in activated CD8+T-cells (Figure 6A). Treatment of CD8+T-cells with CGS-21680 24 h after incubation with anti-CD3 ϵ /CD28 antibodies had no effect on Notch1 protein levels (Figures 6B–D). Proliferation and release of granzyme B and IFN- γ from activated CD8+T-cells were unchanged by CGS-21680 treatment once the early TCR signal had been transduced (Figures 6E–G, respectively).

To determine whether A2AR agonists affect later stages of the TCR signaling cascade leading to Notch1 activation, we activated CD8+T-cells with PMA and ionomycin. PMA and ionomycin induce protein kinase C (PKC) activity and Ca⁺⁺ influx (39). CD8+T-cells activated with PMA and ionomycin showed much higher levels of Notch1TM and N1ICD compared to unstimulated cells (Figures 7A–C). In addition, treatment of these cells with CGS-21680 (1 μ M) before stimulation with PMA and ionomycin had no effect on Notch1 protein levels (Figures 7A–C), suggesting that A2AR acts upstream of PKC activation during TCR-induced Notch activation. Taken together,

these results indicate that the suppressive effects of CGS-21680 through A2AR on Notch1 activation rely in its capacity to block early TCR signaling events upstream of PKC activation, most likely ZAP70 phosphorylation. These effects are lost once TCR signals have been transduced and the first wave of N1ICD generation has occurred.

DISCUSSION

In the present study we describe a previously unknown role for the A2A adenosine receptor pathway in the control of TCR-induced Notch1 receptor activation in CD8+T-cells. Stimulation of A2AR decreases the levels of Notch1 receptor protein stabilized by TCR ligation, as well as the levels of cleaved active intracellular domain generated in CD3 ϵ /CD28-stimulated CD8+T-cells. This effect requires A2AR and is mediated by inhibition of TCR signaling upstream of PKC activation.

Consistent with published results (22, 26), activation of A2AR increases intracellular levels of cAMP. cAMP-dependent

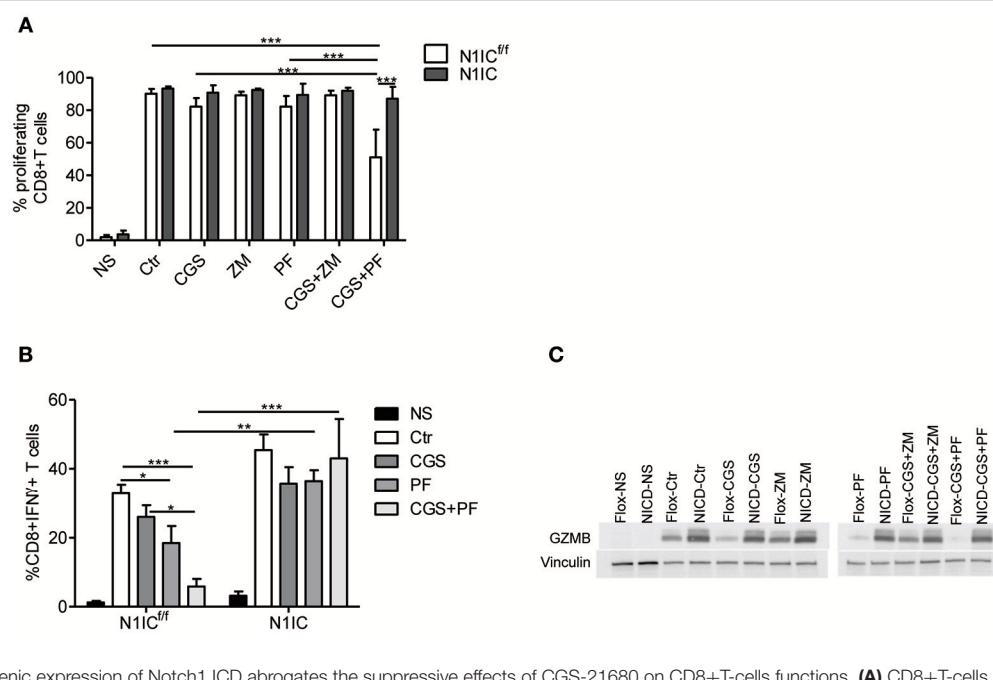

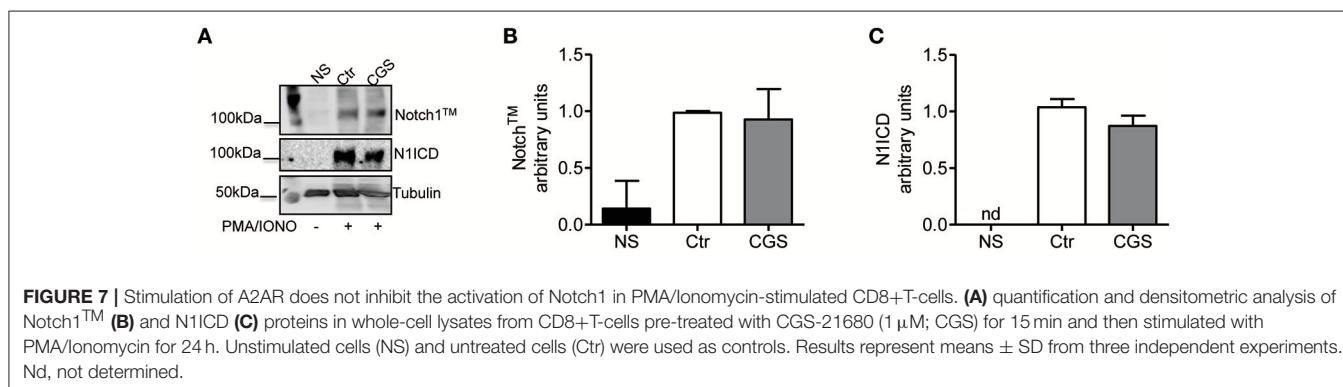

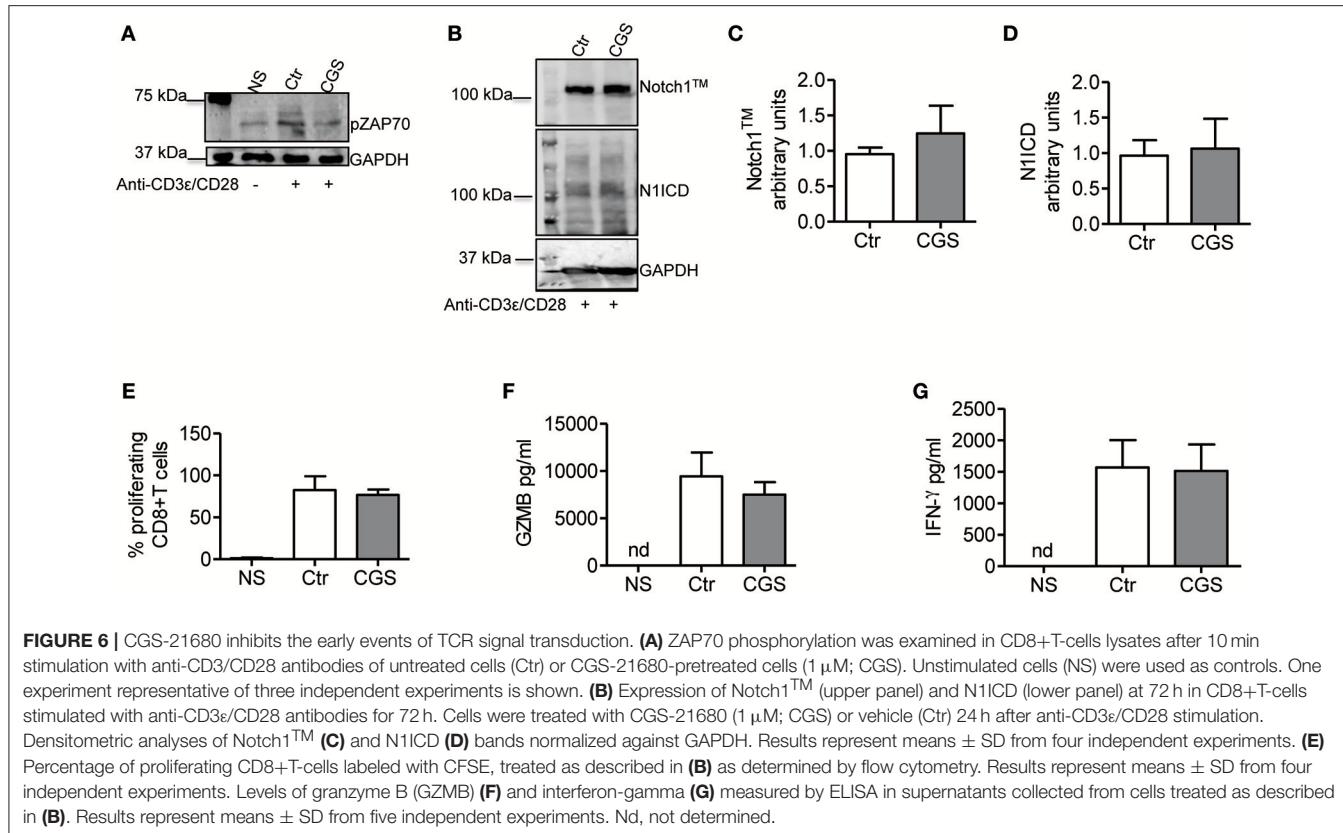

FIGURE 5 | Transgenic expression of Notch1 ICD abrogates the suppressive effects of CGS-21680 on CD8+T-cells functions. **(A)** CD8+T-cells isolated from spleen of N1IC^{ff} or N1IC mice were activated with anti-CD3/CD28 antibodies and 24 h later cells were labeled with CFSE and incubated in presence or absence of: CGS-21680 (1 μ M; CGS); PF-3084014 (1 μ M; PF); CGS in combination with PF (CGS+PF); or ZM-241385 (1 μ M; ZM) alone or in combination with CGS. CD8+T-cells proliferation was assessed after 72 h by flow cytometry. Results represent means \pm SD of the percentage of proliferating cells from three independent experiments. *** p < 0.001; two-way ANOVA followed by Bonferroni correction for multiple comparisons. **(B)** Expression of IFN- γ was assessed in cells stimulated as described in **(A)**. The percentage of CD8+IFN- γ +T-cells was determined by flow cytometry. Results represent means \pm SD from four independent experiments. * p < 0.05; ** p < 0.01; *** p < 0.001; two-way ANOVA followed by Bonferroni correction for multiple comparisons. **(C)** CD8+T-cells from N1IC^{ff} or N1IC mice were stimulated as described in **(A)**, whole-cells extracts were collected and expression of granzyme B (GZMB) was determined by Western blotting. Blot representative of two independent experiments is shown.

protein kinase A (PKA) phosphorylates and activates the C-terminal SRC kinase (CSK), which in turn phosphorylates and inactivates Lck, reducing tyrosine phosphorylation of the TCR/CD3 ζ chain during T-cells activation (40). Lck-mediated tyrosine phosphorylation of the TCR/CD3 ζ chain after T-cell activation is required for the recruitment to CD3 and activation of the zeta-chain-associated protein kinase 70 (ZAP70) and subsequent activation of other substrates that initiate downstream signals (40). In line with previous data (26, 41), stimulation of A2AR with CGS-21680 reduced ZAP70 phosphorylation. Therefore, we propose a mechanism whereby stimulation of A2AR, by attenuating early TCR transduction signaling in a cAMP-dependent manner, can prevent the generation of the Notch1 intracellular domain (N1ICD) induced by TCR signaling in CD8+T-cells (Figure 8). This working model could apply not only to A2AR but also potentially to other immune suppressive molecules that signal through cAMP and PKA in T-cells, such as prostaglandin E2 (42, 43).

Our data indicate that A2AR signals act upstream of a diacylglycerol-dependent PKC and Ca $^{++}$, as PMA and ionomycin bypass the effect of A2AR activation upon Notch1. Recent data show that TCR-induced, Notch ligand-independent Notch1 cleavage in T-cells requires the activation of one or more PKC isoforms, which facilitate ADAM activity (11). Previous

reports indicate that the activities of ADAM10 and 17, involved in the S2 Notch1 cleavage (44) are regulated by PKC α and PKC θ (45, 46). Activation of PKC is a downstream event of the TCR signaling, which depends on diacylglycerol produced by phospholipase C (PLC)- γ . PLC- γ activation in turn is triggered by the phosphorylation of ZAP70 (47). The stable activation and membrane translocation of PKC θ requires Vav and phosphatidylinositol 3-kinase (PI3K) activation, triggered by the CD28 costimulatory signal, in addition to TCR/CD3 signal (47). PKC θ , a Ca $^{++}$ -independent, phospholipid-dependent PKC isoform, is a central player in the immunological synapse, responsible for the activation of AP-1 and NF- κ B downstream of the TCR (48). In this study, we observed that activation of CD8+T-cells with PMA and ionomycin, which directly and potently stimulate the activity of PKCs (47), increases the levels of Notch1 and consequently its activity. This is similar to what was described by Steinbuck and collaborators (11) in CD4+ T-cells. Our data indicate that the process of Notch1 activation in CD8+ T-cells is likely similar to what these authors described, involving a ZAP70-dependent, ligand-independent endocytosis process that results in Notch internalization and cleavage in the endosomal compartment. Notch endocytosis can result in either endosomal γ -secretase cleavage and release of N1ICD into the cytoplasm or lysosomal degradation of uncleaved receptor. E3 ubiquitin ligases Deltex (DTX1) in

mammals) and Suppressor of Deltex (*Itchy* in mice and AIP4 in humans) target Notch1 to endosomal activation or lysosomal degradation, respectively [see (49, 50) for reviews]. In many mammalian cells, inactive Notch receptors are constitutively targeted to lysosomal degradation via Itchy/AIP4 (50). In T-cells, E3 ligase Cbl ubiquitinates Notch1 and Notch3 and targets them to lysosomal degradation (51, 52). Interestingly, PKC θ phosphorylates and inactivates Cbl (47), and PI3K-AKT protects Notch1 from Cbl-induced degradation in T-ALL (51). The fact that in our cells Notch1 protein was virtually undetectable at rest but rapidly increased and was cleaved to generate N1ICD upon TCR activation suggests that TCR signals in CD8+ T-cells can shift Notch1 protein from a

default rapid lysosomal degradation pathway, perhaps mediated by Cbl-catalyzed ubiquitination, to an endosomal activation pathway, and that A2AR modulates this process via cAMP. Further investigations on these mechanisms may help to better understand how adenosine, and possibly other cAMP-generating immune suppressive mediators, regulate Notch1 activity in CD8+T-cells.

The effect of CGS-21680 on Notch1 expression is A2AR-dependent, since it was completely reversed by a selective A2AR antagonist and lost in CD8+T-cells from A2AR $-/-$ mice. A2AR activation with CGS-21680 markedly inhibits the production of IFN- γ and granzyme B released from CD3 ϵ /CD28-stimulated CD8+T-cells. These data are consistent with previous studies

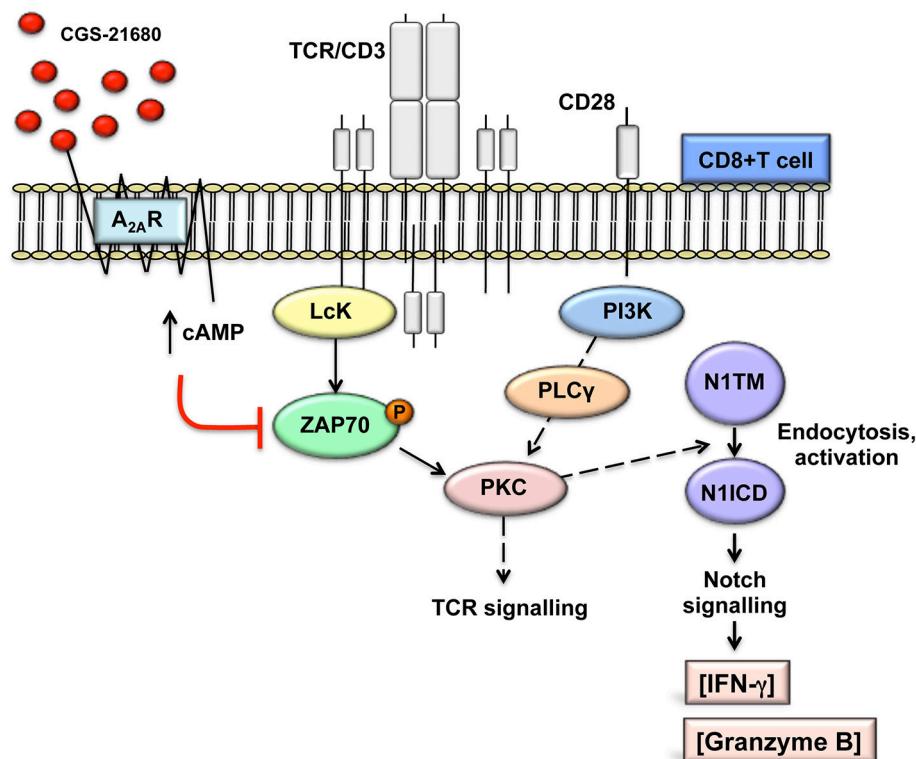

FIGURE 8 | Working model: A2AR stimulation prevents TCR-induced generation of Notch1 intracellular domain by attenuating early TCR signaling events in a cAMP-dependent manner. This prevents PKC-induced Notch1 endosomal activation. Since no Notch ligands were used in our experimental system, we propose that Notch1 activation follows a ligand-independent, endosomal mechanism as described in CD4+ T-cells. The PKC isoform involved has not been determined. In turn, reduced Notch1 signaling results in decreased expression of direct and indirect Notch target genes, such as granzyme B and INF- γ , thereby impairing the effector functions of activated CD8+T-cells. This model is consistent with our observations that direct stimulation of PKC-induced Notch1 activation with PMA and ionomycin bypasses cAMP-mediated inhibition and that inducible expression of N1ICD abrogates the effects of A2AR stimulation. We have not determined whether cAMP causes Notch1 to be targeted for lysosomal degradation.

describing a critical role of A2AR in controlling CD8+T-cell activation in a cAMP-dependent manner, by suppressing proximal TCR signaling events (18, 53). These effects as well were completely lost in activated CD8+T-cells from *A2AR*^{-/-} mice, as well as in wild-type cells incubated with CGS-21680 after TCR stimulation.

In CD4+ T-cells, Notch augments NF-κB activity after TCR activation (36). Moreover, Notch1 is required for CD8 effector functions, including production of IFN- γ and granzyme B (10). GSIs suppress production of IFN- γ and granzyme B (30). Consistent with published observations, GSI PF-3084014 did decrease production of IFN- γ and granzyme B in CD8+ T-cells. Our data show that simultaneous inhibition of Notch and stimulation of A2AR profoundly impair the responses of activated CD8+T-cells, including proliferation and cytokine production. This suggests that in tumor microenvironments rich in adenosine and other immune-suppressive mediators, GSIs may suppress anti-tumor CD8+ responses. GSIs have multiple targets (14), including Notch2, which is also induced by TCR stimulation in T-cells although to a lesser extent than Notch1 (54). Our data show that CD8+ T-cells ectopically expressing

N1IC are remarkably resistant to the inhibitory effects of A2AR stimulation compared with controls N1IC^{f/f} cells. These results strongly indicate that intracellular levels of Notch1 regulate the sensitivity of CD8+ T-cells to A2AR agonists, and that inhibition of Notch1 is a functionally relevant mechanism whereby A2AR agonists suppress CD8+ T-cell activation. Whether A2AR antagonists can protect Notch activity in CD8+ T-cells in tumors remains to be determined. Further investigations are also required to understand whether the A2AR signaling suppresses responses in other T-cell subsets, including CD4+T-cells and memory CD4+ or CD8+ T-cells, through inhibition of Notch.

Altogether, our data suggest a new role for A2AR in blunting Notch activity, which is essential to the effector function of CD8+T-cells. We propose that the inhibitory effects of CGS-21680 on activated CD8+ T-cells are, at least partially, dependent on reduced Notch1 protein and activity after TCR stimulation. This novel cross-talk between two critical pathways offers new insights into the mechanisms whereby elevated adenosine concentrations can hamper immune cell activation in tumors and/or in inflamed injured tissues.

ETHICS STATEMENT

All animal studies were carried out in Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC)—accredited facilities in the context of protocols approved by the Institutional Animal Care and Use Committees of LSUHSC-New Orleans, the Moffitt Comprehensive Cancer Center and Northeastern University, respectively.

AUTHOR CONTRIBUTIONS

SM and LM conceived the study, supervised experiments, and prepared the final version of the manuscript. CS, FH, AP, and RS performed experiments and interpreted their results. PR supervised experiments in Notch1IC-transgenic T-cells, which were performed by RS. BO and LMM provided expertise on TCR signaling and PKC activity, contributed to result interpretation, reviewed and edited the final version of the manuscript.
